Principle of Impulse and Momentum for Rigid Body Motion (2D)

General Plane Motion

The figure shows a rigid body moving in two dimensions. The motion is caused by a series of N forces \vec{F}_i ($i=1, \dots, N$). Generally, each force has the effect of **translating** and **rotating** the body. Newton's laws of translational and rotational motion are

$$\sum_i \vec{F}_i = m \vec{a}_G = m \left(\frac{d\vec{v}_G}{dt} \right) = \frac{d}{dt} (m \vec{v}_G)$$

$$\sum_i (\vec{M}_G)_i = \sum_i (\vec{r}_i \times \vec{F}_i) = I_G \alpha = I_G \left(\frac{d\omega}{dt} \right) = \frac{d}{dt} (I_G \omega)$$

Note here that $(\vec{M}_G)_i$ represents the **moment** of force \vec{F}_i about the mass center G . Also, recall that I_G represents the **moment of inertia** of the body about a Z axis passing through the mass center G .

The above equations can be **integrated with respect to time** to give

$$\boxed{(m \vec{v}_G)_1 + \int_{t_1}^{t_2} \left(\sum_i \vec{F}_i \right) dt = (m \vec{v}_G)_2} \quad \text{(Principle of Linear Impulse & Momentum)}$$

$$\boxed{(I_G \omega)_1 + \int_{t_1}^{t_2} \left(\sum_i (\vec{r}_i \times \vec{F}_i) \right) dt = (I_G \omega)_2} \quad \text{(Principle of Angular Impulse & Momentum)}$$

The **principle of linear impulse and momentum** states that the linear impulses applied to the body over the **time interval** $t_1 \rightarrow t_2$ give rise to a **change** in the linear momentum of the body. The **principle of angular impulse and momentum** states that the angular impulses applied to the body over the **time interval** $t_1 \rightarrow t_2$ give rise to a **change** in the angular momentum of the body. Note that the linear momentum is often written as $\vec{L} = m \vec{v}_G$, and the angular momentum about the mass center G as $\vec{H}_G = I_G \omega$.

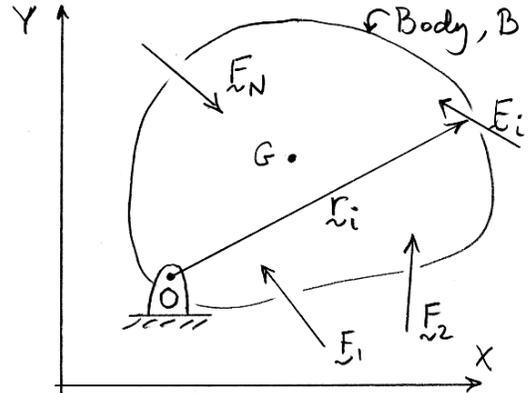

Note that, like Newton's laws of translational and rotational motion, the above equations are **vector equations**. For planar motion, there are **two scalar linear momentum equations** (X and Y directions) and **one scalar angular momentum equation** (Z direction).

Special Case

Fixed Axis Rotation

When a body is undergoing *fixed axis rotation* as shown, the principle of angular momentum can be written about the fixed point O as

$$\boxed{(I_O \omega)_1 + \int_{t_1}^{t_2} \left(\sum_i (\underline{r}_i \times \underline{F}_i) \right) dt = (I_O \omega)_2}$$

In this case, $\sum_i (\underline{r}_i \times \underline{F}_i)$ represents the moment of all the forces about the fixed point O , and I_O represents the moment of inertia of the body about a Z axis passing through O .

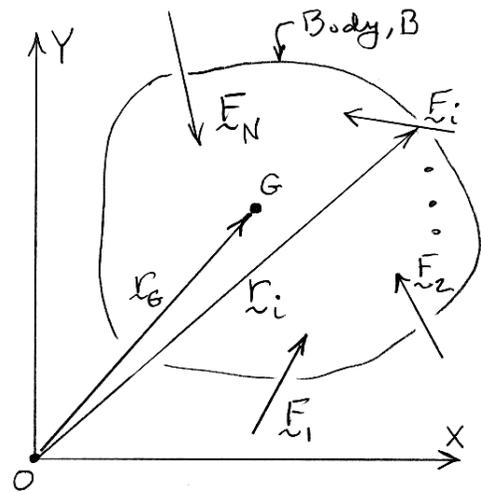

Principle of Angular Momentum about an Arbitrary Fixed Point

Consider a rigid body undergoing planar motion. The principle of angular impulse and momentum can also be written relative to an arbitrary fixed point O as follows

$$\boxed{(\underline{H}_O)_1 + \int_{t_1}^{t_2} \left(\sum_i (\underline{r}_i \times \underline{F}_i) \right) dt = (\underline{H}_O)_2}$$

where

$$\boxed{\underline{H}_O = I_G \omega + (\underline{r}_G \times m \underline{v}_G)}$$

Note that \underline{H}_O is the sum of the angular momentum of the body about G and the moment of the linear momentum about O (assuming that $\underline{L} = m \underline{v}_G$ acts through G).
