

## Introductory Control Systems

### Summary Procedure for the Root Locus Diagram

1. Write the characteristic equation:  $1 + GH(s) = 0$

Rewrite the equation in the form:  $1 + kP(s) = 0$

Root Locus (RL):  $0 \leq k \leq +\infty$

Simple Closed Loop System

2. Find the **poles** and **zeros** of  $P(s)$ . The root loci start at the poles and proceed to the zeros as  $k$  advances from  $0 \rightarrow \infty$ .

- The number of branches (loci) on the RL diagram is equal to  $n_p$ , the number of poles.
- The number of asymptotes is  $n_A = n_p - n_z$ . ( $n_z$  is the number of zeros)

3. Plot the **pole-zero diagram** for  $P(s)$ . Then,

- Identify those segments of the real axis that contain roots of the characteristic equation. There are roots on those segments such that an **odd** number of poles and zeros are to the right of that segment.
- Identify the direction of movement of the poles. The poles of the closed loop system move from the poles of  $P(s)$  to the zeros of  $P(s)$  (or to infinity) as  $K$  increases from  $0 \rightarrow \infty$ .

4. Calculate the **angles of all asymptotes** (if any):

$$\phi_A = \left[ \frac{2m+1}{n_p - n_z} \right] 180^\circ \quad (m = 0, 1, 2, \dots, (n_p - n_z - 1))$$

5. Calculate the **intersection point** of the asymptotes with the real axis (if any):

$$\sigma_A = \frac{\sum (\text{pole locations}) - \sum (\text{zero locations})}{n_p - n_z}$$

6. **Sketch** the branches of the root locus diagram. Keep in mind that the root loci are **symmetric** with respect to the **real axis**.

7. Calculate the locations of the **break points** (if any):

Define:  $p(s) = -1/P(s)$       Set:  $\frac{dp(s)}{ds} = 0$  **or**  $\frac{dP(s)}{ds} = 0$  and solve for  $s$ .

8. **Angles of Departure** and **Arrival** of the Root Loci:

- The angle of the tangent to the root locus at any point must satisfy the angle condition: The **difference** between the sum of the angles of the vectors drawn to the point from the poles of  $P(s)$  and the sum of the angles of the vectors drawn to it from the zeros of  $P(s)$  is an **odd multiple of  $180^\circ$** .
- At a pole of  $P(s)$ , the angle is called an angle of departure. At a zero of  $P(s)$ , the angle is called an angle of arrival.
